

Curves of Pursuit

Four mice start on the four corners of a square and chase their nearest anticlockwise neighbour at the same speed. As their chase progresses, the mice gradually spiral towards the square's centre along curves known as **logarithmic spirals**. These curves can be approximated by the corners of a succession of squares, each drawn inside the previous, as shown below. The corners of each square are placed a fixed percentage of the distance along the edges of the previous square. For example, the distance between a new corner and the corner of the previous square is 5% of the previous square's edge length.
